Engine Valve Train Spring Design

The basic valve spring is a single wire, cylinder shaped spring. The ends of the spring are ground flat to sit flush on the spring seat and retainer. However, in a performance application, the single wire spring rarely provides the loads required to control valvetrain operation.

Camshaft lobe profile has the largest role in spring selection.

Out of the many components in an engine, valve springs might not look like much, but they are hands down some of the hardest working parts. Choosing between linear, single coil, dual coil, beehive, or conical springs depends on your application, the rpm range, camshaft characteristics, and anticipated spring pressures.

At slow speeds when the valve is opening and closing, compressing the valve spring is the main activity that creates a force in the valvetrain. As the engine speed increases, the pushrod and rocker arm are required to move the

Studying Valvetrain Motion and Dynamics

In essence, the valvetrain design situation boils down to the struggle between cam lobe designer and spring engineer. Within this tug-of-war, the cam designer is the heavyweight. It is well within his ability to design a cam that generates brutal acceleration and/or velocity rates.

Depending on the design used, the valves are actuated by a rocker arm, finger or bucket tappet. Overhead camshaft engines use fingers or bucket tappets, upon which the cam lobes contact. Overhead valve engines use rocker arms, which are actuated by a pushrod and pivot on a shaft or individual ball studs in order to actuate the valves.

Valvetrain - Wikipedia

A desmodromic valve is a reciprocating engine poppet valve that is positively closed by a cam and leverage system, rather than by a more conventional spring. The valves in a typical four-stroke engine allow the air/fuel mixture into the cylinder at the beginning of the cycle and exhaust gases to be expelled at the end of the cycle. In a conventional four-stroke engine valves are opened by a cam and closed by return spring. An engine using desmodromic valves has two cams and two actuators, each f

nents of the valve train must:

- Remain stable over the entire service life
- Run with a low level of friction in their guides

Valve Springs. The purpose of the valve spring is to maintain contact between the components in the valve train, so the valve motion will follow the cam profile. This is most important during the deceleration portion of the cam motion, since the inertia forces in the valve train are opposed to the spring forces.

With the LVTS, you can precisely identify, document and record crucial characteristics of the valve train such as valve bounce, lofting, spring harmonics, and pushrod deflection. To use the LVTS, first create a baseline valve trace by tracking the valve at a stable engine speed (typically 2,000 - 3,000 RPM).
